## Programming Assignment 5: down the stack (the network interface)

**Due:** May 10, 2024. 23:59  
**Late deadline:** May 11, 2024. 23:59 (20% penalty)

### 1. Overview

In this assignment, you’ll go down the stack and implement a network interface: the bridge between Internet datagrams that travel the world, and link-layer Ethernet frames that travel one hop. This component can fit “underneath” your TCP/IP implementation from the earlier assignments, but it will also be used in a different setting: when you build a router in Assignment 6, it will route datagrams *between* network interfaces. Figure 1 shows how the network interface fits into both settings.

In past assignments, you wrote a TCP implementation that can successfully exchange **TCP segments** with any other computer that speaks TCP. How are these segments actually conveyed to the peer’s TCP implementation? As we’ve discussed, there are a few options:

- **TCP-in-UDP-in-IP.** The TCP segments can be carried in the payload of a user datagram. When working in a normal (user-space) setting, this is the easiest to implement: Linux provides an interface (a “datagram socket”, `UDPSocket`) that lets applications supply *only the payload* of a user datagram and the target address, and the kernel takes care of constructing the UDP header, IP header, and Ethernet header, then sending the packet to the appropriate next hop. The kernel makes sure that each socket has an exclusive combination of local and remote addresses and port numbers, and since the kernel is the one writing these into the UDP and IP headers, it can guarantee isolation between different applications.
- **TCP-in-IP.** In common usage, TCP segments are almost always placed directly inside an Internet datagram, without a UDP header between the IP and TCP headers. This is what people mean by “TCP/IP.” This is a little more difficult to implement. Linux provides an interface, called a TUN device, that lets application supply an *entire* Internet datagram, and the kernel takes care of the rest (writing the Ethernet header, and actually sending via the physical Ethernet card, etc.). But now the application has to construct the full IP header itself, not just the payload.
- You’ve done this already. In Assignment 4, we gave you an object that represents an Internet datagram and knows how to parse and serialize itself (`tcp_helpers/ipv4_datagram.{hh,cc}`) and the logic to encapsulate TCP segments in IP (now found in `tcp_helpers/tcp_over_ip.cc`). The `CS144TCPsocket` uses these tools to connect your `TCPConnection` to a TUN device.

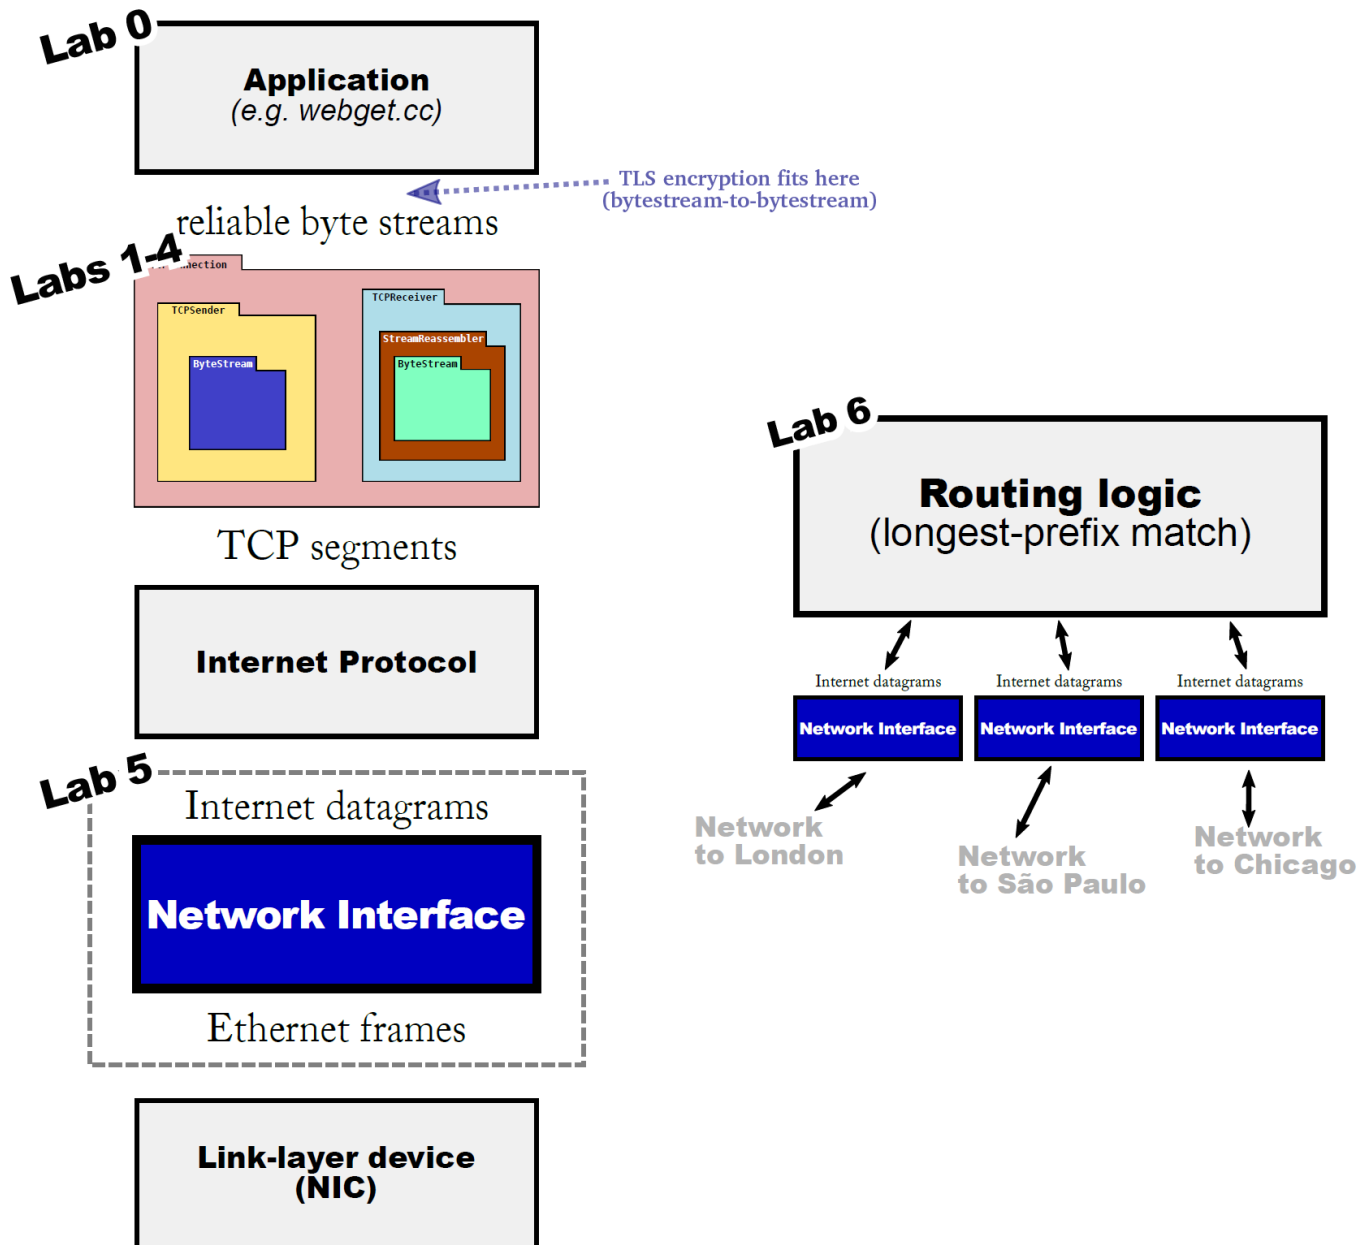

Figure 1: The network interface bridges the worlds of Internet datagrams and of link-layer frames. This component is useful as part of a host's TCP/IP stack (left side), and also as part of an IP router (right side).

- **TCP-in-IP-in-Ethernet.** In the above approach, we’re still relying on the Linux kernel for part of the networking stack. Each time your code writes an IP datagram to the TUN device, Linux has to construct an appropriate link-layer (Ethernet) frame with the IP datagram as its payload. This means Linux has to figure out the next hop’s Ethernet destination address, given the IP address of the next hop. If it doesn’t know this mapping already, Linux broadcasts a query that asks, “Who claims the following IP address? What’s your Ethernet address?” and waits for a response.
- These functions are performed by the *network interface*: a component that translates outbound IP datagrams into link-layer (e.g., Ethernet) frames and vice versa. (In a real system, network interfaces typically have names like `eth0`, `eth1`, `wlan0`, etc.) **In this assignment**, you’ll implement a network interface, and stick it at the very bottom of your TCP/IP stack. Your code will produce raw Ethernet frames, which will be handed over to Linux through an interface called a TAP device—similar to a TUN device, but more low-level, in that it exchanges raw link-layer frames instead of IP datagrams.

Most of the work will be in looking up (and caching) the Ethernet address for each next-hop IP address. The protocol for this is called the **Address Resolution Protocol**, or **ARP**.

We’ve given you unit tests that put your network interface through its paces. Then, at the end of this assignment, you’ll slightly modify your `webget` to use your TCP implementation, *running on your network interface*, so that the whole thing produces raw Ethernet frames and can still talk to a real webserver across the Internet. In Assignment 6, you’ll use the same network interface outside the context of TCP, as a part of an IP router.

## 2. Getting started

1. Make sure you have committed all your solutions to Assignment 4. Please don’t modify any files outside the top level of the `libsponge` directory, or `webget.cc`. (And please don’t add extra files that your code relies upon.) You may have trouble merging the Assignment 5 starter code otherwise.
2. While inside the repository for the assignments, run `git fetch` to retrieve the most recent version of the assignments.
3. Download the starter code for Assignment 5 by running `git merge origin/lab5-startercode`.
4. Within your `build` directory, compile the source code: `make` (you can run, e.g., `make -j4` to use four processors when compiling).
5. Outside the `build` directory, open and start editing the `writeups/assn5.md` file. This is the template for your assignment writeup and will be included in your submission.

### 3. The Address Resolution Protocol

Before you get to coding, please read:

- The [public interface for the `NetworkInterface` object](#).
- Wikipedia's [summary of ARP](#) and the original [ARP specification \(RFC 826\)](#).
- The documentation/implementation of the [EthernetFrame](#) and [EthernetHeader](#) objects.
- The documentation and implementation of the [IPv4Datagram](#), and [IPv4Header](#) objects (which can parse and serialize an Internet datagram, and when serialized, can be assigned to the payload of an Ethernet frame).
- The documentation and implementation of the [ARPMessage](#) object (which knows how to parse and serialize an ARP message, and can also serve as the payload of an Ethernet frame when serialized).

Your main task in this assignment will be to implement the three main methods of `NetworkInterface` (in the `network_interface.cc` file), maintaining a mapping from IP addresses to Ethernet addresses. The mapping is a cache, or “soft state”: the `NetworkInterface` keeps it around for efficiency's sake, but if it has to restart from scratch, the mapping will naturally be regenerated without causing a problem.

1. `void NetworkInterface::send_datagram(const InternetDatagram &dgram, const Address &next_hop)`

This method is called when the caller (e.g., your `TCPConnection` or a router) wants to send an outbound Internet (IP) datagram to the next hop.<sup>1</sup> It's your interface's job to translate this datagram into an Ethernet frame and (eventually) send it.

- *If the destination Ethernet address is already known*, send it right away. Create an Ethernet frame (with `type = EthernetHeader::TYPE_IPv4`), set the payload to be the serialized datagram, and set the source and destination addresses.
- *If the destination Ethernet address is unknown*, broadcast an ARP request for the next hop's Ethernet address, and queue the IP datagram so it can be sent after the ARP reply is received.

**Except:** You don't want to flood the network with ARP requests. If the network interface already sent an ARP request about the same IP address in the last five seconds, don't send a second request – just wait for a reply to the first one. Again, queue the datagram until you learn the destination Ethernet address.

---

<sup>1</sup> Please don't confuse the *ultimate* destination of the datagram, which is in the datagram's own header as the destination address, with the next hop. In this assignment you're *only* going to care about the next hop's address.

2. `optional<InternetDatagram> NetworkInterface::recv_frame(const EthernetFrame &frame)`

This method is called when an Ethernet frame arrives from the network. The code should ignore any frames not destined for the network interface (meaning, the Ethernet destination is either the broadcast address or the interface's own Ethernet address stored in the `_ethernet_address` member variable).

- *If the inbound frame is IPv4*, parse the payload as an `InternetDatagram` and, if successful (meaning the `parse()` method returned `ParseResult::NoError`), return the resulting `InternetDatagram` to the caller.
- *If the inbound frame is ARP*, parse the payload as an `ARPMessage` and, if successful, remember the mapping between the sender's IP address and Ethernet address for 30 seconds. (Learn mappings from both requests and replies.) In addition, if it's an ARP request asking for our IP address, send an appropriate ARP reply.

3. `void NetworkInterface::tick(const size_t ms_since_last_tick)`

This is called as time passes. Expire any IP-to-Ethernet mappings that have expired.

**You can test your implementation by running** `ctest -V -R "^arp"`. This test does not rely on your TCP implementation.

## 4. webget re<sup>2</sup>visited

Remember your `webget.cc` that you wrote in Assignment 0 (using the Linux-provided TCP implementation in `TCPSocket`)? And, remember how you modified it in Assignment 4 to use your own TCP-in-IP implementation in `CS144TCPSocket`? As we discussed above, this still relies on the Linux kernel for part of the stack: the network interface that translates between IP and the link layer (Ethernet).

We'd like you to switch it to use your network interface without changing anything else. you'll need to do is replace the `CS144TCPSocket` type with `FullStackSocket`.

This uses a TCP-in-IP-in-Ethernet stack as shown in a Figure 1 (left side): your `webget.cc` application, on top of your `TCPConnection` implementation of TCP, on top of the TCP-in-IP code in [tcp\\_helpers/tcp\\_over\\_ip.cc](#), on top of your `NetworkInterface`.

Recompile, and run `make check_lab5` to confirm that you've gone full-stack: you've written a basic Web fetcher on top of *your own complete TCP implementation* and *your own network interface implementation*, and it still successfully talks to a real webserver.

If you have trouble, try running the program manually:

`./apps/webget cs144.keithw.org /hasher/xyzyzy`, and try capturing what it's sending and receiving by using `wireshark`. You can save the packets it's sending and receiving by running `sudo tcpdump -i tap10 -w /tmp/packets.tap`. Then open the `/tmp/packets.tap` file in `wireshark`.

## 5. Q & A

- *How much code are you expecting?*

Overall, we expect the implementation (in `network_interface.cc`) will require about 100–150 lines of code in total.

- *How does the `NetworkInterface` actually send an Ethernet frame?*

Similar story to how the `TCPsender` and `TCPConnection` worked. For the `NetworkInterface`, push any outbound frame to the `_frames_out` queue and it will be popped and sent by the object's owner.

- *What data structure should I use to record the mapping between next-hop IP address and Ethernet addresses?*

Up to you!

- *How do I convert an IP address that comes in the form of an `Address` object, into a raw 32-bit integer that I can write into the ARP message?*

Use the `Address::ipv4_numeric()` method.

- *What should I do if the `NetworkInterface` sends an ARP request but never gets a reply? Should I resend it after some timeout? Signal an error to the original sender using ICMP?*

In real life, yes, both of those things, but don't worry about that in this assignment. (In real life, an interface will eventually send an ICMP "host unreachable" back across the Internet to the original sender if it can't get a reply to its ARP requests.)

- *What should I do if an `InternetDatagram` is queued waiting to learn the Ethernet address of the next hop, and that information never comes? Should I drop the datagram after some timeout?*

Again, definitely a "yes" in real life, but don't worry about that in this assignment.

- *How do I run the test suite for this assignment?*

`make check_lab5` (two tests). Or you can run the entire test suite with `make check` (160 tests).

## 6. Submit

1. In your submission, please only make changes to the `.hh` and `.cc` files in the top level of `libsponge`, and `apps/webget.cc`. Within these files, please feel free to add private members as necessary, but please don't change the *public* interface of any of the classes.
2. Please don't add extra files-the automatic grader won't look at them and your code may fail to compile.
3. **Please don't forget** to change your `webget` to use a `FullStackSocket` (instead of the `CS144TCPSocket` that you used in Assignment 4, or the kernel's `TCPSocket` in Assignment 0).

4. Before handing in any assignment, please run these in order:
  - (a) `make format` (to normalize the coding style)
  - (b) `git status` (to check for un-committed changes—if you have any, commit!)
  - (c) `make` (to make sure the code compiles)
  - (d) `make check_lab5` (to make sure the automated tests pass)
5. Write a report in `writeups/assn5.md`. This file should be a roughly 20-to-50-line document with no more than 80 characters per line to make it easier to read. The report should contain the following sections:
  - (a) **Program Structure and Design.** Describe the high-level structure and design choices embodied in your code. You do not need to discuss in detail what you inherited from the starter code. Use this as an opportunity to highlight important design aspects and provide greater detail on those areas for your grading TA to understand. You are strongly encouraged to make this writeup as readable as possible by using subheadings and outlines. Please do not simply translate your program into an paragraph of English.
  - (b) **Implementation Challenges.** Describe the parts of code that you found most troublesome and explain why. Reflect on how you overcame those challenges and what helped you finally understand the concept that was giving you trouble. How did you attempt to ensure that your code maintained your assumptions, invariants, and preconditions, and in what ways did you find this easy or difficult? How did you debug and test your code?
  - (c) **Remaining Bugs.** Point out and explain as best you can any bugs (or unhandled edge cases) that remain in the code.
6. In your writeup, please specify the usage of best-submission codes, if you have used **any**.

**Caution:** When specifying your usage of best codes, you should include all of the best codes that exist in not only your current Assignment but **also in any part of your past Assignment that you are building upon**. The below figure shows examples of how to specify the usage of best codes.

Assignment #0	Assignment #1	...	Assignment #N-2	Assignment #N-1	Assignment #N	
Your implementation	Your implementation		Your implementation	Best code implementation	Your implementation	☞ Specify #N-1
Your implementation	Your implementation		Best code implementation	Best code implementation	Your implementation	☞ Specify #N-1, #N-2
Your implementation	Best code implementation		Your implementation	Best code implementation	Your implementation	☞ Specify #N-1, #1
Your implementation	Your implementation		Your implementation	Your implementation	Your implementation	☞ Purely yours. No need to specify.

If your submission is not purely yours, your score will be capped at 90% of the full score, and your code is not a candidate for the best code selection. This penalty persists unless you replace all the best codes you used **with your implementation**.

7. In your writeup, please also fill in the number of hours the assignment took you and any

other comments.

8. When you have finished your implementation, do not forget to **commit all changes you made!** This **should be done before creating an archive** of your git repository. If you create an archive before committing changes, the archive will include only part or none of the changes you made. This may result in a lower score than you anticipated, or worse zero.

If you are unsure whether your archive includes all changes you made, please refer to our Q&A item: [How do I make sure the created bundle includes all my commits?](#).

9. To archive your repository, use the following command to archive your git repository:

```
git bundle create /tmp/<your_student_id>.git --all
```

**Important:** this command will create an archive of your git history, which means that your solution must be committed to your git repository! In addition, we will be grading only the master branch of your repository, so please be sure that branch corresponds to the solution you want to turn in.

10. Please upload your bundle file to the proper assignment entry on PLMS.
